

Functional Area Resource Intensity Weight Proportions

Methodology Notes and Glossary — Case Mix Group

Introduction

This document provides an overview of the methodology used by the Canadian Institute for Health Information (CIHI) to produce national resource estimates (proportions) for functional areas by Case Mix Group (CMG). These proportions may be used in combination with the Resource Intensity Weights (RIWs) to estimate resource use per functional area for each CMG.

The estimated proportions and corresponding variation measures are presented by functional area and by CMG in the electronic client tables on the [Case mix web page](#) of CIHI's website. Please see the appendix for a description of the functional areas.

Please consult the document [DAD Resource Intensity Weights and Expected Length of Stay for CMG+ 2022](#) for specific information related to the RIW methodology.

How to use the functional area RIW proportions to estimate resource use

Say you are the clinical manager of an obstetrics unit. You want to better understand the costs incurred in your inpatient nursing unit. Most of your patients are grouped into the following 2 CMGs:

- 559 — Primary Caesarean Section
- RIW: 0.6969
- 563 — Vaginal Delivery
- RIW: 0.4246

Using the client table, you will see that for the CMGs you are interested in, the functional area proportions are as follows:

CMG	Inp Nursing Services	Outp Nursing Services	Operating and Recovery Room Nursing Services	Total Nurs	Clinical Lab	Medical Imaging	Other Professional Services	Indirect Costs	Grand Total
559 — Primary Caesarean Section	60%	0%	6%	66%	4%	0%	2%	28%	100%
563 — Vaginal Delivery	69%	0%	0%	69%	3%	0%	1%	27%	100%

You can see that the proportion of total nursing costs is very similar for the 2 patient groups — 66% and 69%.

Patients grouped to CMG 563 incurred all of their nursing costs within the inpatient nursing services functional area, while patients in CMG 559 also incurred costs in the operating and recovery room nursing functional area.

For a patient in CMG 559, the relative cost weight representing the resources expended on nursing services is calculated as follows:

- $0.66 \times 0.6969 = 0.4599$

The relative cost weight spent on operating and recovery room nursing services is 6%, or $0.06 \times 0.6969 = 0.0418$.

You also know that the cost of a standard hospital stay (CSHS)ⁱ for your hospital is \$5,983. Therefore, the estimated average cost for a patient grouped to CMG 559 is calculated as follows:

- $0.6969 \times \$5,983 = \$4,170$

The total nursing services cost is estimated as follows:

- $0.66 \times \$4,170 = \$2,752$

Of this, \$1,651 is for inpatient nursing services and \$165 is for operating and recovery room nursing services.

i. This indicator was formerly called Cost per Weighted Case (CPWC).

The total estimated average cost for a patient in CMG 563 is calculated as follows:

- $0.4246 \times \$5,983 = \$2,540$

Furthermore, for a patient in CMG 563, total nursing services accounted for 69% of the total estimated average cost, with a relative cost weight of 0.2930, or \$1,753.ⁱⁱ

Please consult the document [Cost of a Standard Hospital Stay: Appendices to Indicator Library — Methodology Notes](#) for specific information related to the CSHS methodology.

The data

To complete the calculations, CIHI used clinical data from the Discharge Abstract Database (DADⁱⁱⁱ), which was grouped using the CMG+ 2022 grouping methodology, and patient cost data from the Canadian Patient Cost Database (CPCD^{iv}). 2 years of data were used to include sufficient volumes to provide stable estimates: Nova Scotia (2017–2018 and 2018–2019), Ontario (2017–2018 and 2018–2019) and Alberta (2017–2018 and 2018–2019). Statistics Canada’s Consumer Price Index was used to inflate 2016–2017 cost records from the Hospital for Sick Children by 2.7% to approximate 2018–2019 costs.

The patient cost data was collected in accordance with the *Standards for Management Information Systems in Canadian Health Service Organizations* (MIS Standards) 2016.^v The same cost data was used to develop the RIW and expected length of stay (ELOS) products for CMG+ 2022.

Please note that for the purposes of this product, only typical cases were included. Typical means the hospital inpatient had a normal and expected course of treatment. Unexpected outcomes, such as deaths, transfers or long stays, were excluded.

The table below provides a summary of the volume of typical acute inpatient cases used in the calculations, by province and fiscal year.

ii. Data in the example is for illustration purposes only.

iii. The DAD contains data on hospital discharges across Canada.

iv. The CPCD contains patient-level cost data from 4 provinces.

v. The MIS Standards is the accounting standard for Canadian health service organizations.

Table Typical acute inpatient case volumes used for functional area RIW proportions calculation

Fiscal year	Province	Volume of cases
2017	Nova Scotia	22,589
2017	Ontario	708,965
2017	Alberta	224,605
2018	Nova Scotia	22,664
2018	Ontario	654,241
2018	Alberta	194,278

Please note that CMGs containing diagnoses and/or procedures related to termination of pregnancy (CMG 546 to 555) are suppressed in the client tables.

Methodology

CIHI underwent a consultation process with CPCD data providers to define the functional areas and develop methodologies to address specific data quality challenges, such as the lack of comparability in the case of pharmacy costs.

Functional areas

Using the functional centres from the MIS Standards in the cost data, CIHI defined 7 functional areas:^{vi}

- Inpatient nursing services (N)
- Outpatient nursing services (A)
- Operating and recovery room nursing services (O)
- Clinical laboratory (L)
- Medical imaging (G)
- Other professional services (P)
- Indirect costs (I)

vi. See the appendix for detailed functional area definitions (by MIS functional centre).

According to the MIS Standards, the simultaneous equation allocation method is used to allocate costs in administrative functional centres to the patient care functional centres. In patient costing, these costs are further allocated to the patient, resulting in patient cost records that contain both direct and indirect costs within the patient care functional centres.

The indirect costs functional area includes all costs reported on the patient cost record in the administrative and support services functional centres (71 1 ** **), as well as any indirect costs that were allocated to the patient care functional centres. Thus all costs reported within each of the other functional areas are direct costs.

Please see the appendix for functional area definitions.

Allocation of pharmacy and drug costs to nursing functional areas

At the patient cost record level, pharmacy and drug costs are allocated to the relevant nursing functional centres to maximize comparability. Specifically, costs captured under the pharmacy functional centres (71 4 40 **) are allocated to the inpatient nursing services, outpatient nursing services, and operating and recovery room nursing services functional areas based on the distribution of the direct costs of each functional area (N, A and O) as a proportion of total nursing functional areas.

Calculating the proportions

The resource estimates by functional area and CMG are generated by aggregating patient costs for each functional area by CMG. The proportions of cost for each functional area in each CMG, describing the distribution of costs within each CMG, are calculated by dividing each functional area's total dollar cost by the total dollar cost for the CMG. Finally, each estimated proportion is accompanied by a variance measure to provide additional information to the user.

Data limitations

1. Low volume: Some CMG cells contain fewer than 30 observations, creating unstable estimates in those cases.
2. Lack of comparability: There is some inconsistency in the patient costing methodology employed at the facility and jurisdictional levels in capturing drug-related and pharmacy costs. It was decided that costs within the 71 4 40 ** functional centres (pharmacy, prescription and wardstock drug costs) would be included with the nursing functional areas, since this is a reporting requirement of the MIS Standards. Improved reporting is expected to address this issue and allow for the future creation of a drugs functional area.

Assessment of variance in estimates

For the user to assess the precision of the proportions, confidence intervals are provided.

Variability can be looked at in 2 ways: relative and absolute. The confidence interval provides a relative measure. The importance of each way of looking at variability depends on the situation and how the proportions are used.

Calculating variation measures

To calculate variance, patient-level cost data (by functional area for each CMG) was used to estimate the confidence intervals of the average cost per patient for the functional area of each CMG. The average cost calculations need to include both zeros and non-zeros, so patient cost records remained in the calculations even when they reported no cost in a functional area.

The estimated proportional resource consumption of a functional area is calculated by dividing the average cost per patient for the functional area by the total average cost per patient. For the reported variability measures, the calculations are initially done on the dollar scale; the dollar scale values for the measure are then re-scaled to be the percentage (relative to total scale for the CMG). In the interactive table provided, the user can enter the facility-level CSHS to see the confidence intervals estimated at the facility level, based on facility costs and on the national average typical RIW.^{vii} Users may also enter facility-specific RIWs to further refine the estimates.

Estimates for certain CMGs vary widely, so their confidence intervals may include negative values. For this analysis, a negative confidence interval limit was converted to 0. Similarly, confidence interval limits higher than 100% were set at 100%.

Assumption

This conversion of the variability measures from the dollar scale to the proportion scale (percentage) treats the average total cost within each CMG as a constant when, in fact, it is an estimate and subject to variation. This means that both the numerators and denominators of the proportions have some variability. This analysis focuses on the variability of the numerators when calculating the estimates in percentage. Thus the random effect on the denominator is taken out by treating the total costs in each CMG as constant. In this case, the numerator and denominator can be expected to be positively correlated, which makes these confidence intervals somewhat conservative.

vii. National average RIW was calculated using the RIW values from all patient abstracts submitted to the DAD in 2018 representing typical acute care inpatient stays.
